WO02083925

Publication Title:

PAPAYA RINGSPOT VIRUS GENES

Abstract:

The present invention relates to the isolation and identification of nucleic acid sequences encoding the coat protein of papaya rinspot virus in the Kapoho (KA), Keaau (KE), Thailand (TH), Brazil (BR), Jamaica (JA), Mexico (ME), Venezuela (VE), and Oahu (OA) strains, and the uses thereof to impart viral resistance to papaya plants. The present invention also relates to nucleic acid constructs containing individual or multiple papaya ringspot virus coat protein-encoding nucleic acid sequences, and host cells and transgenic plants and seeds containing such constructs. The present invention is also directed to a method of using such constructs to impart to plants resistance to papaya ringspot virus.

The present invention is also directed to a method of using such constructs to impart to plants resistance to papaya ringspot virus.

PAPAYA RINGSPOT VIRUS GENES

FIELD OF THE INVENTION

The present invention relates to the isolation and purification of nucleic acid sequences encoding for papaya ringspot virus coat proteins, a method of conferring resistance to papaya ringspot virus by transforming plants with a construct containing one or more isolated viral coat protein nucleic acid sequences, and transgenic plants and seeds transformed with such multiple virus nucleic acid constructs.

BACKGROUND OF THE INVENTION

Papaya (*Carica papaya L.*) is an important fruit crop grown widely in tropical and subtropical lowland regions (Manshardt, "Papaya in Biotechnology of Perennial Fruit Crops," ed. Hammerschlag, 21:489-511, CAB Int., Wallingford, UK (1992)). Worldwide, Brazil, India, and Mexico are the largest producers of papaya. Hawaii, the largest producer of papaya in the United States, exports 66% of the total fresh production, primarily to the U.S. mainland and to Japan (Martin, "Papaya Production Statistics," Proc. Annu. Hawaii Papaya Ind. Assoc. Conf., 39th, Kihei, pp. 31-36, Sept. 23-24 (1994)). In total production, papaya ranks above strawberries and below grapefruit (Manshardt, "Papaya in Biotechnology of Perennial Fruit Crops," ed. Hammerschlag, 21:489-511, CAB Int., Wallingford, UK (1992)). The FAO estimated that about 5.7 million metric tons of fruit were harvested in 1995, almost double the 1980 harvest (Galinsky, "World Market for Papaya," Reg. Agribus. Proj. Mark. Inf. Bull. Feb. No. 12, 5 pp. (1996)).

Papaya ringspot virus ("PRSV") is a member of the potyvirus group of plant viruses, which are pathogenic to several crop plants, and which exhibit cross-infectivity between members of different plant families. Generally, a potyvirus is a single-stranded (+) RNA plant virus. The viral genome is approximately 10,000 bases in length. The expression strategy of potyviruses includes translation of a complete polyprotein from the positive sense viral

genomic RNA. PRSV is by far the most widespread and damaging virus that infects papaya, occurring worldwide wherever papaya is grown (Purcifull, "Papaya Ringspot Virus," CMI/AAB Descr. Plant Viruses, No. 292 (No. 84 Revis., July 1984) 8 pp. (1984)). PRSV infections have resulted in the devastation of the papaya industry in Brazil, Taiwan, and Hawaii in recent years (Gonsalves, D., "Control of Papaya Ringspot Virus in Papaya: A Case Study," Annu. Rev. Phytopathol. 36:415-37 (1998)). Various attempts have been made to control or prevent infection of crops by PRSV, but these have been largely unsuccessful.

The concept of parasite-derived resistance ("PDR"), conceived in the middle 1980s, offered a new approach for controlling PRSV (Sanford et al., "The Concept of Parasite-Derived Resistance - Deriving Resistance Genes from the Parasite's Own Genome," J. Theor. Biol. 113:395-405 (1985)). Parasite-derived resistance is a phenomenon whereby transgenic plants containing genes or sequences of a parasite are protected against detrimental effects of the same or related pathogens. The application of PDR for plant viruses was first demonstrated when transgenic tobacco expressing the coat protein gene of tobacco mosaic virus was protected against infection by tobacco mosaic virus (Powell-Abel et al., "Delay of Disease Development in Transgenic Plants that Express the Tobacco Mosaic Virus Coat Protein Gene," Science, 232:738-43 (1986)). Subsequent reports have shown that this approach is effective in controlling many plant viruses (Lomonossoff, G.P., "Pathogen-Derived Resistance to Plant Viruses," Ann. Rev. Phytopathol. 33:323-43 (1995)).

The vast majority of reports regarding PDR have utilized the coat protein genes of the viruses that are targeted for control. Although the testing of transgenic plants have been largely confined to laboratory and greenhouse experiments, a growing number of reports have shown that resistance is effective under field conditions (Grumet, R., "Development of Virus Resistant Plants via Genetic Engineering," Plant Breeding Reviews 12:47-49 (1994)). Two virus resistant crops have been deregulated by the Animal and Plant Heath Information Service of the United States Department of Agriculture ("USDA/APHIS") and, thus, are approved for unrestricted release into the environment in the U.S. Squash that are resistant to watermelon mosaic virus 2 and zucchini yellow mosaic potyviruses have been commercialized (Fuchs et al., "Resistance of

Transgenic Hybrid Squash ZW-20 Expressing the Coat Protein Genes of Zucchini Yellow Mosaic Virus and Watermelon Mosaic Virus 2 to Mixed Infections by Both Potyviruses," Bio/Technology 13:1466-73 (1995); Tricoli, et al., "Field Evaluation of Transgenic Squash Containing Single or Multiple Virus Coat Protein Gene Constructs for Resistance to Cucumber Mosaic Virus, Watermelon Mosaic Virus 2, and Zucchini Yellow Mosaic Virus," Bio/Technology 13:1458-65 (1995)). A transgenic Hawaiian papaya that is resistant to PRSV has also been developed (Fitch et al., "Virus Resistant Papaya Derived from Tissues Bombarded with the Coat Protein Gene of Papaya Ringspot Virus," Bio/Technology 10:1466-72 (1992); Tennant et al., "Differential Protection Against Papaya Ringspot Virus Isolates in Coat Protein Gene Transgenic Papaya and Classically Cross-Protected Papaya," Phytopathology 84:1359-66 (1994)). This resistant transgenic papaya was recently deregulated by USDA/APHIS. Deregulation of the transgenic papaya is timely, because Hawaii's papaya industry is being devastated by PRSV.

Remarkable progress has been made in developing virus resistant transgenic plants despite a poor understanding of the mechanisms involved in the various forms of pathogen-derived resistance (Lomonossoff, G.P., "Pathogen-Derived Resistance to Plant Viruses," Ann. Rev. Phytopathol. 33:323-43 (1995)). Although most reports deal with the use of coat protein genes to confer resistance, a growing number of reports have shown that genes encoding viral replicase (Golemboski et al., "Plants Transformed with a Tobacco Mosaic Virus Nonstructural Gene Sequence are Resistant to the Virus," Proc. Natl. Acad. Sci. USA 87:6311-15 (1990)), movement protein (Beck et al., "Disruption of Virus Movement Confers Broad-Spectrum Resistance Against Systemic Infection by Plant Viruses with a Triple Gene Block," Proc. Natl. Acad. Sci. USA 91:10310-14 (1994)), nuclear inclusion a-proteases ("NIa proteases") of potyviruses (Maiti et al., "Plants that Express a Potyvirus Proteinase Gene are Resistant to Virus Infection," Proc. Natl. Acad. Sci. USA 90:6110-14 (1993)), and other viral genes are also effective in conferring resistance. Furthermore, viral genes can be effective in the translatable and non-translatable sense forms, and, less frequently, antisense forms (Baulcombe, D.C., "Mechanisms of Pathogen-Derived Resistance to Viruses in Transgenic Plants," Plant Cell 8:1833-44 (1996); Dougherty et al., "Transgenes and Gene Suppression: Telling us Something New?" Current

Opinion in Cell Biology 7:399-05 (1995); Lomonossoff, G.P., "Pathogen-Derived Resistance to Plant Viruses," Ann. Rev. Phytopathol. 33:323-43 (1995)).

Notwithstanding the progress made in the field of plant resistance to viral pathogens, PRSV continues to exert its devastating effect upon papaya and other crops the world over. While the transgenic Hawaiian papaya is controlling the problem temporarily in Hawaii, that line unfortunately appears to susceptible to PRSV isolates with origins outside Hawaii. These observations suggest that transgenic papaya with coat protein genes specific to targeted PRSV isolates would need to be developed for transgenic papaya to effectively control PRSV worldwide. A more practical and comprehensive approach is needed to halt the devastation of PRSV. Such an approach would impart resistance to PRSV by utilizing genetic engineering techniques to provide greater and more reliable multi-pathogen resistance to crops to PRSV and other RNA-viral plant pathogens.

The present invention is directed to overcoming these and other deficiencies in the art.

SUMMARY OF THE INVENTION

The present invention relates to isolated nucleic acid molecules encoding a viral coat protein of papaya ringspot virus and the protein encoded by those nucleic acid molecules.

Another aspect of the present invention pertains to nucleic acid constructs containing the isolated nucleic acid molecules of the present invention operably linked to 5' and 3' regulatory regions.

The present invention also relates to nucleic acid constructs containing a plurality of trait DNA molecules, wherein at least some of the plurality of trait DNA molecules have a length that is insufficient to independently impart that trait to plants transformed with that trait DNA molecule. However, the plurality of trait DNA molecules are capable of collectively imparting their traits to plants transformed with the DNA construct and thereby effecting the silencing of the DNA construct. The trait associated with the DNA molecules of this construct is disease resistance, and the trait DNA molecules are derived from a gene encoding a papaya ringspot virus coat protein in a papaya ringspot virus

strain selected from the group consisting of Thailand ("TH"), Keaau ("KE"), Kapoho ("KA"), Mexico ("ME"), Taiwan ("YK"), Brazil ("BR"), Jamaica ("JA"), Oahu ("OA"), and Panaewa ("PA").

The present invention also relates to a DNA construct containing a fusion gene which includes a trait DNA molecule which has a length insufficient to independently impart a desired trait to plants transformed with the trait molecule, operatively coupled to a silencer molecule effective to achieve post-transcriptional gene silencing. The trait DNA molecule and the silencer molecule collectively impart the trait to plants transformed with the construct. The DNA molecules of this DNA construct are derived from a gene encoding a papaya ringspot viral coat protein from a papaya ringspot virus strain selected from the group consisting of TH, KE, KA, ME, YK, BR, JA, OA, and VE.

The present invention also relates to host cells, plant cells, transgenic plants, and transgenic plant seeds containing the nucleic acid constructs of the present invention.

The present invention also relates to a method of imparting resistance against papaya ringspot virus to papaya plants. This involves transforming a papaya plant with the constructs of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

Figures 1A-B show the cloning vectors used for the DNA constructs of the present invention. Figure 1A shows the expression cassette, pEPJ-YKT, containing the PRSV-CP variable regions of the YK, KE, and TH strains ligated into the pEPJ vector. Figure 1B shows the transformation vector pGA482G.

Figures 2A-B show the expression vectors used for cloning and subcloning the silencer-PRSV-CP construct. Figure 2A shows the pNP-YKT vector, containing the silencer DNA molecule (*M1/2NP*) and the *PRSV-CP* variable regions of PRSV strains YK, KE, and TH. Figure 2B shows the pGFP-YKT vector, containing the silencer molecule *GFP* ligated to the *PRSV-CP* variable regions of PRSV strains YK, KE, and TH PRSV strains.

Figures 3A-G show various *PRSV-CP* DNA molecules ligated to the silencer molecule (*M 1/2 NP*) in an expression vector. Figure 3A shows clone pNP-K; Figure 3B shows clone pNP-KK; Figure 3C shows clone pNP-EE; Figure 3D shows clone pNP-KKTC; Figure 3E shows clone pNP-KKTV; Figure 3F shows clone pNP-EETC, and Figure 3G shows clone pNP-EETV.

Figure 4A shows the a full-length (1 Kb) *KE-CP* DNA molecule encoding a translatable RNA for PRSV-CP ligated into the expression vector pEPJ. Figure 4B shows a full-length (1 Kb) *KE-CP* DNA molecule encoding a non-translatable RNA for PRSV-CP ligated into the expression vector pEPJ.

Figure 5 shows a 855 bp *NcoI/Bam*HI Mexico *PRSV-CP* DNA molecule ligated into the expression vector pEPJ.

DETAILED DESCRIPTION

The present invention relates to nucleic acids which encode for a viral coat protein ("CP") of papaya ringspot virus ("PRSV").

One suitable form of the nucleic acid of the present invention is the *CP* gene isolated from the PRSV strain Kapoho ("KA"), which has a nucleic acid sequence corresponding to SEQ ID NO: 1 as follows:

Also suitable as a nucleic acid for use in the present invention is the nucleic acid which encodes a *CP* gene isolated from the Keaau ("KE") strain of PRSV. PRSV-KE contains two "cut-sites", i.e., two potential cleavage sites for a mature coat protein. The first cleavage site sequence in the KE strain of PRSV, identified herein as *KE-CP1*, corresponds to SEQ ID NO: 5 (*KECP1*) as follows:

```
tcaaggagca ctgatgatta tcaacttgtt tggagtgaca atacacatgt gtttcatcag 60

SEQ ID NOS: 5 and 6 contain, respectively, the N terminus and C terminus cleavage sites for PRSV-KE coat protein. Both cleavage sites result in proteins that appear to be functional in viral replication in the plant. SEQ ID NO: 5 encodes the first coat protein cleavage site product, CP1, of the KE strain of PRSV. KE-CP1 has an amino acid sequence corresponding to SEQ ID NO: 7, as follows:

```

Also suitable for use in the present invention are variants of the nucleic acid molecules shown above. An example of a suitable nucleic acid is a nucleic acid molecule which has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of the SEQ ID NOS: 1, 3, 5, 6, 9, 11, 13, 15, 17, and 19 by basic BLAST using default parameters analysis, or which hybridizes to the nucleotide sequence of SEQ ID NOS: 1, 3, 5, 6, 9, 11, 13, 15, 17, and 19 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of about 42°-65°C, preferbly 45°C.

Fragments of genes encoding PRSV-CP are particularly useful in the present invention. Fragments capable of use in the present invention can be produced by several means. In one method, subclones of the gene encoding the CP of choice are produced by conventional molecular genetic manipulation by subcloning gene fragments. In another approach, based on knowledge of the primary structure of the protein, fragments of a PRSV-CP encoding gene may be synthesized by using the PCR technique together with specific sets of primers chosen to represent particular portions of the protein. These, then, would be cloned into an appropriate vector in either the sense or antisense orientation.

Another example of suitable fragments of the nucleic acids of the present invention are fragments of the genes which have been identified as conserved ("con") regions of the CP proteins, or alternatively, those portions of PRSV-CP nucleotide sequences that have been identified as variable ("var") regions. Sequences identified using DNAStar Mega alignment program as either variable or conserved in a PRSV-CP gene can be amplified using standard PCR

methods using forward and reverse primers designed to amplify the region of choice and which include a restriction enzyme sequence to allow ligation of the PCR product into a vector of choice. Combinations of amplified conserved and variable region sequences can be ligated into a single vector to create a "cassette" which contains a plurality of DNA molecules in one vector. The use of conserved and variable regions of PRSV-CP DNA is further detailed below in the Examples.

The present invention also relates to a DNA construct that contains a DNA molecule encoding for a PRSV-CP isolated from any of a variety of PRSV strains, most preferably the TH, KA, KE, YK, ME, BR, JA, OA, and VE strains. This involves incorporating one or more of the nucleic acid molecules of the present invention, or a suitable portion thereof, of the nucleic acid corresponding to SEQ ID NOS: 1, 3, 5, 6, 9, 11, 13, 15, 17, and 19 into host cells using conventional recombinant DNA technology. Generally, this involves inserting the nucleic acid molecule into an expression system to which the nucleic acid molecule is heterologous (i.e., not normally present). The heterologous nucleic acid molecule is inserted into the expression system which includes the necessary elements for the transcription and translation of the inserted protein coding sequences.

The nucleic acid molecules of the present invention may be inserted into any of the many available expression vectors and cell systems using reagents that are well known in the art. Suitable vectors include, but are not limited to, the following viral vectors such as lambda vector system gt11, gt WES.tB, Charon 4, and plasmid vectors such as pBR322, pBR325, pACYC177, pACYC1084, pUC8, pUC9, pUC18, pUC19, pLG339, pR290, pKC37, pKC101, SV 40, pBluescript II SK +/- or KS +/- (see "Stratagene Cloning Systems" Catalog (1993) from Stratagene, La Jolla, CA, which is hereby incorporated by reference in its entirety), pQE, pIH821, pGEX, pET series (see Studier et. al., "Use of T7 RNA Polymerase to Direct Expression of Cloned Genes," Gene Expression Technology vol. 185 (1990), which is hereby incorporated by reference in its entirety), and any derivatives thereof. Recombinant molecules can be introduced into cells via transformation, particularly transduction, conjugation, mobilization, or electroporation. The DNA sequences are cloned into the vector using standard cloning procedures in the art, as described by Sambrook et al.,

Molecular Cloning: A Laboratory Manual, Second Edition, Cold Spring Harbor Press, NY (1989), and Ausubel, F. M. et al. (1989) Current Protocols in Molecular Biology, John Wiley & Sons, New York, N.Y., which are hereby incorporated by reference in their entirety.

In preparing a DNA vector for expression, the various DNA sequences may normally be inserted or substituted into a bacterial plasmid. Any convenient plasmid may be employed, which will be characterized by having a bacterial replication system, a marker which allows for selection in a bacterium, and generally one or more unique, conveniently located restriction sites. Numerous plasmids, referred to as transformation vectors, are available for plant transformation. The selection of a vector will depend on the preferred transformation technique and target species for transformation. A variety of vectors are available for stable transformation using *Agrobacterium tumefaciens*, a soilborne bacterium that causes crown gall. Crown gall are characterized by tumors or galls that develop on the lower stem and main roots of the infected plant. These tumors are due to the transfer and incorporation of part of the bacterium plasmid DNA into the plant chromosomal DNA. This transfer DNA ("T-DNA") is expressed along with the normal genes of the plant cell. The plasmid DNA, pTi, or Ti-DNA, for "tumor inducing plasmid," contains the *vir* genes necessary for movement of the T-DNA into the plant. The T-DNA carries genes that encode proteins involved in the biosynthesis of plant regulatory factors, and bacterial nutrients (opines). The T-DNA is delimited by two 25 bp imperfect direct repeat sequences called the "border sequences." By removing the oncogene and opine genes, and replacing them with a gene of interest, it is possible to transfer foreign DNA into the plant without the formation of tumors or the multiplication of *Agrobacterium tumefaciens* (Fraley, et al., "Expression of Bacterial Genes in Plant Cells," Proc. Nat'l Acad. Sci. 80:4803-4807 (1983), which is hereby incorporated by reference in its entirety).

Further improvement of this technique led to the development of the binary vector system (Bevan, M., "Binary *Agrobacterium* Vectors for Plant Transformation," Nucleic Acids Res. 12:8711-8721 (1984), which is hereby incorporated by reference in its entirety). In this system, all the T-DNA sequences (including the borders) are removed from the pTi, and a second vector containing

T-DNA is introduced into *Agrobacterium tumefaciens*. This second vector has the advantage of being replicable in *E. coli* as well as *A. tumefaciens*, and contains a multiclonal site that facilitates the cloning of a transgene. An example of a commonly used vector is pBin19 (Frisch, et al., "Complete Sequence of the Binary Vector Bin19," Plant Molec. Biol. 27:405-409 (1995), which is hereby incorporated by reference in its entirety). Any appropriate vectors now known or later described for genetic transformation are suitable for use in the present invention.

U.S. Patent No. 4,237,224 issued to Cohen and Boyer, which is hereby incorporated by reference in its entirety, describes the production of expression systems in the form of recombinant plasmids using restriction enzyme cleavage and ligation with DNA ligase. These recombinant plasmids are then introduced by means of transformation and replicated in unicellular cultures including prokaryotic organisms and eukaryotic cells grown in tissue culture.

Certain "control elements" or "regulatory sequences" are also incorporated into the vector-construct. These include non-translated regions of the vector, promoters, and 5' and 3' untranslated regions which interact with host cellular proteins to carry out transcription and translation. Such elements may vary in their strength and specificity. Depending on the vector system and host utilized, any number of suitable transcription and translation elements, including constitutive and inducible promoters, may be used.

A constitutive promoter is a promoter that directs expression of a gene throughout the development and life of an organism. Examples of some constitutive promoters that are widely used for inducing expression of transgenes include the nopoline synthase ("NOS") gene promoter, from *Agrobacterium tumefaciens*, (U.S. Patent 5034322 to Rogers et al., which is hereby incorporated by reference in its entirety), the cauliflower mosaic virus ("CaMV") 35S and 19S promoters (U.S. Patent No. 5,352,605 to Fraley et al., which is hereby incorporated by reference in its entirety), the enhanced CaMV35S promoter ("enh CaMV35S"), the figwort mosaic virus full-length transcript promoter ("FMV35S"), those derived from any of the several actin genes, which are known to be expressed in most cells types (U.S. Patent No. 6,002,068 to Privalle et al., which is hereby incorporated by reference in its entirety), and the ubiquitin

promoter ("ubi"), which is a gene product known to accumulate in many cell types.

An inducible promoter is a promoter that is capable of directly or indirectly activating transcription of one or more DNA sequences or genes in response to an inducer. In the absence of an inducer, the DNA sequences or genes will not be transcribed. The inducer can be a chemical agent, such as a metabolite, growth regulator, herbicide or phenolic compound, or a physiological stress directly imposed upon the plant such as cold, heat, salt, toxins, the action of a pathogen or disease agent such as a virus or fungus. A plant cell containing an inducible promoter may be exposed to an inducer by externally applying the inducer to the cell or plant such as by spraying, watering, heating, or by exposure to the operative pathogen. An example of an appropriate inducible promoter for use in the present invention is a glucocorticoid-inducible promoter ("GIP") (Schena et al., " A Steroid-Inducible Gene Expression System for Plant Cells," Proc. Natl. Acad. Sci. 88:10421-5 (1991), which is hereby incorporated by reference in its entirety). Other useful promoters include promoters capable of expressing potyvirus proteins in an inducible manner or in a tissue-specific manner in certain cell types where infection is known to occur. These include, for example, the inducible promoters from phenylalanine ammonia lyase, chalcone synthase, extensin, pathogenesis-related protein, and wound-inducible protease inhibitor from potato. Other examples of such tissue specific promoters include seed, flower, or root specific promoters as are well known in the field (U.S. Patent No. 5,750,385 to Shewmaker et al., which is hereby incorporated by reference in its entirety). For a review on maximizing gene expression, see Roberts and Lauer, Methods in Enzymology 68:473 (1979), which is hereby incorporated by reference in its entirety.

The particular promoter selected is preferably capable of causing sufficient expression of the DNA coding sequences to which it is operably linked, to result in the production of amounts of the proteins effective to provide viral resistance, but not so much as to be detrimental to the cell in which they are expressed. The actual choice of the promoter is not critical, as long as it has sufficient transcriptional activity to accomplish the expression of the preselected proteins, where expression is desired, and subsequent conferral of viral resistance

to the plants. The promoters selected should be capable of functioning in tissues including, but not limited to, epidermal, vascular, and mesophyll tissues.

The nucleic acid construct of the present invention also includes an operable 3' regulatory region, which provides a functional poly(A) addition signal (AATAAA) 3' of its translation termination codon. This is selected from among those which are capable of providing correct transcription termination and polyadenylation of mRNA for expression in the host cell of choice, operably linked to a DNA molecule which encodes for a protein of choice. A number of 3' regulatory regions are known to be operable in plants. Exemplary 3' regulatory regions include, without limitation, the nopaline synthase 3' regulatory region (Fraley, et al., "Expression of Bacterial Genes in Plant Cells," Proc. Nat'l Acad. Sci. USA 80:4803-4807 (1983), which is hereby incorporated by reference in its entirety) and the cauliflower mosaic virus 3' regulatory region (Odell, et al., "Identification of DNA Sequences Required for Activity of the Cauliflower Mosaic Virus 35S Promoter," Nature 313(6005):810-812 (1985), which is hereby incorporated by reference in its entirety). Virtually any 3' regulatory region known to be operable in plants would suffice for proper expression of the coding sequence of the nucleic acid construct of the present invention.

A vector of choice, suitable promoter, and an appropriate 3' regulatory region can be ligated together to produce the expression systems which contain the nucleic acids of the present invention, or suitable fragments thereof, using well known molecular cloning techniques as described in Sambrook et al., Molecular Cloning: A Laboratory Manual, Second Edition, Cold Spring Harbor Press, NY (1989), and Ausubel et al. (1989) Current Protocols in Molecular Biology, John Wiley & Sons, New York, N.Y., which are hereby incorporated by reference in their entirety.

Once the isolated nucleic acid molecules encoding the various papaya ringspot virus coat proteins or polypeptides, as described above, have been cloned into an expression system, they are ready to be incorporated into a host cell. Such incorporation can be carried out by the various forms of transformation noted above, depending upon the vector/host cell system. Suitable host cells include, but are not limited to, bacteria, virus, yeast, mammalian cells, insect, plant, and the like.

Accordingly, another aspect of the present invention relates to a recombinant plant cell containing one or more of the PRSV-CP nucleic acids of the present invention. Basically, this method is carried out by transforming a plant cell with a nucleic acid construct of the present invention under conditions effective to yield transcription of the DNA molecule in response to the promoter. Methods of transformation may result in transient or stable expression of the DNA under control of the promoter. Preferably, the nucleic acid construct of the present invention is stably inserted into the genome of the recombinant plant cell as a result of the transformation, although transient expression can serve an important purpose, particularly when the plant under investigation is slow-growing.

Plant tissue suitable for transformation include without limitation, leaf tissue, root tissue, meristems, zygotic and somatic embryos, callus, protoplasts, tassels, pollen, embryos, anthers, and the like. The means of transformation chosen is that most suited to the tissue to be transformed.

Transient expression in plant tissue is often achieved by particle bombardment (Klein et al., "High-Velocity Microprojectiles for Delivering Nucleic Acids Into Living Cells," Nature 327:70-73 (1987), which is hereby incorporated by reference in its entirety). In this method, tungsten or gold microparticles (1 to 2 μm in diameter) are coated with the DNA of interest and then bombarded at the tissue using high pressure gas. In this way, it is possible to deliver foreign DNA into the nucleus and obtain a temporal expression of the gene under the current conditions of the tissue. Biologically active particles (e.g., dried bacterial cells containing the vector and heterologous DNA) can also be propelled into plant cells (U.S. Patent Nos. 4,945,050, 5,036,006, and 5,100,792, all to Sanford et al., which are hereby incorporated by reference in their entirety). For papaya, particle gun bombardment has been a particularly successful method (Fitch, M.M., "Stable Transformation of Papaya Via Micro-Projectile Bombardment," Plant Cell Rep. 9:189 (1990), and Fitch et al., "Somatic Embryogenesis and Plant Regeneration from Immature Zygotic Embryos of Papaya (*Carica papaya L.*)," Plant Cell Rep. 9:320 (1990), which are hereby incorporated by reference). Other variations of particle bombardment, now known or hereafter developed, can also be used.

An appropriate method of stably introducing the nucleic acid construct into plant cells is to infect a plant cell with *Agrobacterium tumefaciens* or *Agrobacterium rhizogenes* previously transformed with the nucleic acid construct. As described above, the Ti (or RI) plasmid of *Agrobacterium* enables the highly successful transfer of a foreign DNA into plant cells. Yet another method of introduction is fusion of protoplasts with other entities, either minicells, cells, lysosomes or other fusible lipid-surfaced bodies (Fraley, et al., Proc. Natl. Acad. Sci. USA 79:1859-63 (1982), which is hereby incorporated by reference in its entirety). The DNA molecule may also be introduced into the plant cells by electroporation (Fromm et al., Proc. Natl. Acad. Sci. USA 82:5824 (1985), which is hereby incorporated by reference in its entirety). In this technique, plant protoplasts are electroporated in the presence of plasmids containing the expression cassette. Electrical impulses of high field strength reversibly permeabilize biomembranes allowing the introduction of the plasmids. Electroporated plant protoplasts reform the cell wall, divide, and regenerate. The precise method of transformation is not critical to the practice of the present invention. Any method that results in efficient transformation of the host cell of choice is appropriate for practicing the present invention.

After transformation, the transformed plant cells must be regenerated. Plant regeneration from cultured protoplasts is described in Evans et al., Handbook of Plant Cell Cultures, Vol. 1: (MacMillan Publishing Co., New York, 1983); Vasil I.R. (ed.), Cell Culture and Somatic Cell Genetics of Plants, Acad. Press, Orlando, Vol. I, 1984, and Vol. III (1986), and Fitch et al., "Somatic Embryogenesis and Plant Regeneration from Immature Zygotic Embryos of Papaya (*Carica papaya L.*)," Plant Cell Rep. 9:320 (1990), which are hereby incorporated by reference it their entirety.

It is known that practically all plants can be regenerated from cultured cells or tissues, including but not limited to, all major species of sugarcane, sugar beets, cotton, fruit trees, and legumes.

Means for regeneration vary from species to species of plants, but generally, a suspension of transformed protoplasts or a petri plate containing explants is first provided. Callus tissue is formed and shoots may be induced from callus and subsequently rooted. Alternatively, embryo formation can be induced

in the callus tissue. These embryos germinate as natural embryos to form plants. The culture media will generally contain various amino acids and hormones, such as auxin and cytokinins. Efficient regeneration will depend on the medium, on the genotype, and on the history of the culture. If these three variables are controlled, then regeneration is usually reproducible and repeatable.

Preferably, transformed cells are first identified using a selection marker simultaneously introduced into the host cells along with the nucleic acid construct of the present invention. Suitable selection markers include, without limitation, markers encoding for antibiotic resistance, such as the nptII gene which confers kanamycin resistance (Fraley, et al., Proc. Natl. Acad. Sci. USA 80:4803-4807 (1983), which is hereby incorporated by reference in its entirety), and the genes which confer resistance to gentamycin, G418, hygromycin, streptomycin, spectinomycin, tetracycline, chloramphenicol, and the like. Cells or tissues are grown on a selection medium containing the appropriate antibiotic, whereby generally only those transformants expressing the antibiotic resistance marker continue to grow. Other types of markers are also suitable for inclusion in the expression cassette of the present invention. For example, a gene encoding for herbicide tolerance, such as tolerance to sulfonylurea is useful, or the dhfr gene, which confers resistance to methotrexate (Bourouis et al., EMBO J. 2:1099-1104 (1983), which is hereby incorporated by reference in its entirety). Similarly, "reporter genes," which encode for enzymes providing for production of an identifiable compound are suitable. The most widely used reporter gene for gene fusion experiments has been *uid*A, a gene from *Escherichia coli* that encodes the β-glucuronidase protein, also known as GUS (Jefferson et al., "GUS Fusions: β Glucuronidase as a Sensitive and Versatile Gene Fusion Marker in Higher Plants," EMBO J. 6:3901-3907 (1987), which is hereby incorporated by reference in its entirety). Similarly, enzymes providing for production of a compound identifiable by luminescence, such as luciferase, are useful. The selection marker employed will depend on the target species; for certain target species, different antibiotics, herbicide, or biosynthesis selection markers are preferred.

Plant cells and tissues selected by means of an inhibitory agent or other selection marker are then tested for the acquisition of the viral gene by Southern blot hybridization analysis, using a probe specific to the viral genes

contained in the given cassette used for transformation (Sambrook et al., "Molecular Cloning: A Laboratory Manual," Cold Spring Harbor, New York: Cold Spring Harbor Press (1989), which is hereby incorporated by reference in its entirety).

The presence of a viral coat protein gene can also be detected by immunological assays, such as the double-antibody sandwich assays described by Namba et al., "Expression of the Gene Encoding the Coat Protein of Cucumber Mosaic Virus (CMV) Strain WL appears to Provide Protection to Tobacco Plants Against Infection by Several Different CMV Strains," Gene 107:181-188 (1991), which is hereby incorporated by reference in its entirety, as modified by Clark et al., " Characteristics Of the Microplate Method for Enzyme-Linked Immunosorbent Assay For the Detection of plant Viruses," J. Gen. Virol. 34, 475-83 (1977), which is hereby incorporated by reference in its entirety. Potyvirus resistance can also be assayed via infectivity studies as generally described by Namba et al., "Protection of Transgenic Plants Expressing the Coat Protein Gene of Watermelon Virus ii or Zucchini Yellow Mosaic Virus Against Potyviruses," Phytopath. 82:940946 (1992), which is hereby incorporated by reference in its entirety, wherein plants are scored as symptomatic when any inoculated leaf shows veinclearing, mosaic, or necrotic symptoms.

After the expression cassette is stably incorporated in transgenic plants, it can be transferred to other plants by sexual crossing. Any of a number of standard breeding techniques can be used, depending upon the species to be crossed. Once transgenic plants of this type are produced, the plants themselves can be cultivated in accordance with conventional procedure so that the nucleic acid construct is present in the resulting plants. Alternatively, transgenic seeds or propagules (e.g., cuttings) are recovered from the transgenic plants. These seeds can then be planted in the soil and cultivated using conventional procedures to produce transgenic plants.

The present invention also relates to DNA constructs which contain a plurality of DNA molecules which are derived from one or more genes which encode a papaya ringspot viral coat protein. The *PRSV-CP* DNA molecules may be derived from one or more strains, including, but not limited to, TH, KE, KA, ME, YK, BR, JA, OA, and VE. Some of the *PRSV-CP* DNA molecules may be a

fragment of the nucleic acid sequence of the CP(s) of choice which by itself is too short, i.e., does not contain sufficient nucleotide sequence, to impart its respective trait when placed in an vector and used to transform plant cells as described above. Collectively, however, this plurality of DNA molecules impart their trait to the transformed plant. The trait which is imparted is resistance to the PRSV strain from which any given DNA molecule in the construct is derived. Suitable nucleic acids for this construct include fragments of a PRSV CP-encoding DNA molecule, of any strain, including but not limited to, TH, KE, KA, ME, YK, BR, JA, OA, and VE. The DNA molecules are inserted in the construct as less than full-length DNA, preferably in the range of about 200 bp of the full-length PRSV-CP DNA molecule. The 200 bp fragments are preferably chosen from the conserved and variable regions of CP-encoding DNA. There is no need to include separate promoters for each of the fragments; only a single promoter is required. Moreover, such viral gene fragments can preferably be incorporated in a single expression system to produce transgenic plants with a single transformation event.

The present invention also relates to a DNA construct containing a fusion gene which includes a trait DNA molecule which has a length insufficient to independently impart a desired trait to plants transformed with the trait molecule, operatively coupled to a silencer molecule effective to achieve post-transcriptional gene silencing. The trait DNA molecule and the silencer molecule collectively impart the trait to plants transformed with the construct. The trait DNA molecules of this DNA construct are derived from a gene encoding a papaya ringspot viral coat protein from a papaya ringspot virus strains which include, but are not limited to TH, KE, KA, ME, YK, BR, JA, OA, and VE. The fragments of trait DNA molecules are subcloned into the fusion gene cassette. Suitable DNA fragments are those of about 200 bp which derive from the variable and conserved regions of the CP-encoding molecules of choice. The silencer molecule of the construct of the present invention can be selected from virtually any nucleic acid which effects gene silencing. This involves the cellular mechanism to degrade mRNA homologous to the transgene mRNA. The silencer DNA molecule can be heterologous to the plant, need not interact with the trait DNA molecule in the plant, and can be positioned 3' to the trait DNA molecule. For example, the silencer DNA molecule can be a viral cDNA molecule, including, without

limitation, a gene encoding a replicase, a movement protein, or a nucleocapsid protein; a green fluorescence protein encoding DNA molecule, a plant DNA molecule, or combinations thereof.

In any of the constructs of the present invention, the DNA molecule conferring disease resistance can be positioned within the DNA construct in the sense (5'→3') orientation. Alternatively, it can have an antisense (3'→5') orientation. Antisense RNA technology involves the production of an RNA molecule that is complementary to the messenger RNA molecule of a target gene. The antisense RNA can potentially block all expression of the targeted gene. In the anti-virus context, plants are made to express an antisense RNA molecule corresponding to a viral RNA (that is, the antisense RNA is an RNA molecule which is complementary to a "plus" (+) sense RNA species encoded by an infecting virus). Such plants may show a slightly decreased susceptibility to infection by that virus. Such a complementary RNA molecule is termed antisense RNA.

It is possible for the DNA construct of the present invention to be configured so that the trait and silencer DNA molecules encode RNA molecules which are translatable. As a result, that RNA molecule will be translated at the ribosomes to produce the protein encoded by the DNA construct. Production of proteins in this manner can be increased by joining the cloned gene encoding the DNA construct of interest with synthetic double-stranded oligonucleotides which represent a viral regulatory sequence (i.e., a 5' untranslated sequence) (U.S. Patent No. 4,820,639 to Gehrke, and U.S. Patent No. 5,849,527 to Wilson, which are hereby incorporated by reference in their entirety).

Alternatively, the DNA construct of the present invention can be configured so that the trait and silencer DNA molecules encode mRNA which is not translatable. This is achieved by introducing into the DNA molecule one or more premature stop codons, adding one or more bases (except multiples of 3 bases) to displace the reading frame, removing the translation initiation codon, etc. See U.S. Patent No. 5,583,021 to Dougherty et al., which is hereby incorporated by reference in its entirety. The subject DNA construct can be incorporated in cells using conventional recombinant DNA technology, such as described in detail above.

Another aspect of the present invention is a method to confer resistance to PRSV to plants. This involves transforming susceptible plants with one or more of the nucleic acid constructs of the present invention, testing for transformation using a marker inherent in the vector, selecting transgenics, and regenerating and reproducing the transgenic plants as described above. The expression system of the present invention can be used to transform virtually any plant tissue under suitable conditions. Transformed cells can be regenerated into whole plants such that the PRSV-transgene imparts resistance to PRSV in the intact transgenic plants. In either case, the plant cells transformed with the recombinant DNA expression system of the present invention are grown and caused to express the DNA molecule or molecules in the constructs of the present invention, and, thus, to impart papaya ringspot resistance.

While not wishing to be bound by theory, by use of the constructs of the present invention, it is believed that post-transcriptional gene silencing is achieved. More particularly, the silencer DNA molecule is believed to boost the level of heterologous RNA within the cell above a threshold level. This activates the degradation mechanism by which viral resistance is achieved.

Transgenic plants which show post-transcription gene silencing-derived resistance establish the highly resistant state and prevent virus replication. A chimeric transgene consisting of a silencer DNA (e.g., *GFP*) fused with various small nontranslatable fragment viral genome would be preferred for viral resistance. There are several advantages. First, the silencer DNA can increase the induced gene silencing. Second, the chimeric nature of the gene would provide multiple virus resistance. Third, nontranslatable construction produces no protein, thus reducing the possible complementation of naturally occurring mutants and transencapsidation of other viruses. Fourth, the small fragment also reduces the possibility of recombination with other viral genomes.

Absent a complete understanding of the mechanism(s) of viral resistance conferred through this type of genetic manipulation, optimization of the production of viral resistant transgenics is still under study. Thus, the degree of resistance imparted to a given transgenic plant (high, medium, or low efficacy) is unpredictable. However, it has been noted that when combinations of viral gene expression cassettes are placed in the same binary plasmid, and that multigene

cassette containing plasmid is transformed into a plant, the viral genes all exhibit substantially the same degrees of efficacy when present in transgenic plants. For example, if one examines numerous transgenic lines containing two different intact viral gene cassettes, the transgenic line will be immune to infection by both viruses. Likewise if a transgenic line exhibits a delay in symptom development to one virus, it will also exhibit a delay in symptom development to the second virus. Finally, if a transgenic line is susceptible to one of the viruses it will be susceptible to the other. This phenomenon is unexpected. If there were not a correlation between the efficacy of each gene in these multiple gene constructs, this approach as a tool in plant breeding would probably be prohibitively difficult to use. The probability of finding a line with useful levels of expression can range from 10-50%, depending on the species involved (U.S. Patent No. 6,002,072 to McMaster et al., which is hereby incorporated by reference in its entirety).

The present invention will be further described by reference to the following detailed examples.

EXAMPLES

Example 1– Amplification and Cloning of *CP* Variable Region DNAs

Total RNA was extracted from PRSV-infected papaya plants. Different *PRSV-CP* gene fragments, each about 200 bp, from Taiwan (YK), Keaau (KE), and Thailand (TH) strains were amplified by reverse-transcription and polymerase-chain-reaction (RT-PCR) and extracted from agarose gels. The primers used to amplify the variable region of the PRSV-CP gene of strains YK, KE, and TH are shown in Table 1.

Table 1

PRSV Strain	Product (bp)	Primer position	Primer Sequence (SEQ ID NO)
YKvar	209		
5'YKvarXba		21-39	5' GAGAtctaga TAATGATACCGGTCTGAATGAGAAG 3' (SEQ ID NO: 21)
3'YkvarXho		212-229	5' GGATctcgag AGATCATCTTATCAGTAA 3' (SEQ ID NO: 22)
KEvar	209		
5'KEvarXho		21-39	5' TAGActcgag TGCTGGTTTGAATGAAAAA 3 (SEQ ID NO: 23)
3'KEvarSma		211-229	5' CGATcccggg GAATCAACTTATCAGTAA 3' (SEQ ID NO: 24)
THvar	206		
5'THvarSma		21-39	5' TATAcccggg TGCTGGTCTTAATGAGAAG 3' (SEQ ID NO: 25)
3'THvarBam		209-226	5' CTACggatcc AAATCATCTTGTCGGTAA 3' (SEQ ID NO: 26)

Restriction enzyme sequence is shown in small letters; the stop codon is shown in caps, without underline; viral sequences are underlined.

Following amplification using conventional PCR techniques, the amplified fragments were digested with the appropriate restriction enzymes. A restriction enzyme *Xba*I-*Xho*I digested YK fragment (209 bp) was first ligated into the pEPJ vector. A *Xho*I-*Sma*I digested KE fragment (209 bp) was ligated behind (i.e., at the 3' end of) the YK fragment and then a *Sma*I-*Bam*HI digested TH fragment (206 bp) was ligated behind the KE. The resultant clone, pEPJ-YKT, shown in Figure 1A, contains the variable region of CP from YK-KE-TH in the 5'→ 3' direction. Following a *Hind*III-*Kpn*I restriction digest, the pEPJ-YKT expression cassette was ligated into the *Hind*III-*Kpn*I cloning site of transformation vector pGA482G, shown in Figure 1B, resulting in clone pTi-EPJ-YKT. Cesium chloride purified pTi-EPJ-YKT was then used for host cell transformation by particle gun bombardment.

Example 2 –Cloning of CP Variable Regions into Silencer Construct

Fragments *XbaI/Bam*HI from pEPJ-YKT were ligated into other expression vectors pNP, shown in Figure 2A, and pGFP, shown in Figure 2B, creating pNP-YKT and pGFP-YKT, respectively. "M1/2 NP" shown in Figure 2A refers to a fragment consisting of approximately one half (387-453 bp) of the gene encoding the nucleocapsid protein ("N" or "NP" gene) of the viral genome of the tomato spotted wilt virus ("TSWV"), a tospovirus that causes crop damage worldwide. Expression of large fragments (approximately 1/2 or greater) of the N gene of TSWV have been shown to confer high levels of resistance to TSWV-BL in 20-51% of R1 plants transformed with the fragment, and tolerance to tospovirus infection in 4-22% of R1 plants isolate but not to the distantly related Impatiens necrotic spot virus ("INSV") (Law et al., "The M RNA of Impatiens Necrotic Spot Tospovirus (Bunyaviridae) Has an Ambisense Genomic Organization," Virology, 188:732-41 (1992), which is hereby incorporated by reference in its entirety) or groundnut ringspot virus ("GRSV") (Pang et al., "The Biological Properties of a Distinct Tospovirus and Sequence Analysis of Its mRNA," Phytopathology, 83:728-33 (1993), which is hereby incorporated by reference in its entirety). The N gene of TSWV is an example of a gene derived from the viral genome that is useful as a silencer molecule in the nucleic acid constructs of the present invention. Restriction enzyme *Hind*III/*Kpn*I digested fragments from these two expression vectors were then ligated into the *Hind*III/*Kpn*I cloning site of the transformation vector pGA482G, resulting in clones pTi-NP-YKT and pTi-GFP-YKT. Cesium chloride purified pTi-NP-YKT and pTi-GFP-YKT were then used for host cell transformation by particle gun bombardment.

Example 3 -Amplification and Cloning of CP Conserved Region DNAs

Total RNA was extracted from PRSV-infected papaya plants. Different *PRSV-CP* gene fragments, each about 200 bp, from Keaau (KE) and Thailand (TH) were amplified by RT-PCR. The primers used to amplify the conserved region of the PRSV-CP gene of strains KE and TH are shown in Table 2.

Table 2

PRSV Strain	Product (bp)	Primer position	Primer Sequence (SEQ ID NO)
KEcon	203		
5'KEconXbaSal		649-686	5'TCAAtctagagtcgacGCTAGATATGCTTTCGAC 3' (SEQ ID NO: 27)
3'KEconXhoSal		834-851	5'AAGTctcgaggtcgacCCCAGGAGAGAGTGCATG 3' (SEQ ID NO: 28)
THcon	203	646-683	
5'THconSma			5'AATAcccgggGCTAGATATGCTTTCGAC 3' (SEQ ID NO: 29)
3'THconBam		831-848	5'TTATggatccCCTAGGAGAGAGTGCATG 3 (SEQ ID NO: 30)

Restriction enzyme sequence is shown in small letters; the stop codon is shown in caps, without underline; viral sequences are underlined.

Constructs containing the silencer molecule 1/2 NP are shown in Figures 3A-G. These constructs are designated herein as clone pNP-X_n, where "X" denominates of PRSV strain from which the *CP* DNA is derived, and "n" represents the number fragments of "X" in the cassette. When the DNA is inserted in the sense orientation, "X" is the first initial of the strain, for example, "K" for KE, "T" for TH. When a fragment is inserted in the antisense orientation, the strain acronym is flipped, for example, KE becomes EK, and "X" becomes the first initial of the antisense designation. For example, for an antisense fragment of KE , "X" becomes "E." Translatable and nontranslatable forms of the DNA molecule are further designated with the prefix "TL" and "NTL", respectively.

Clone pNP-K, shown in Figure 3A, was obtained by ligating a single 203 bp *XbaI*/*Xho*I digested KE DNA fragment in a sense orientation into the expression vector pNP containing the 365 bp M1/2NP DNA molecule. Clone pNP-KK, shown in Figure 3B, and pNP-EE, shown Figure 3C, containing sense and antisense KE fragments, respectively, were obtained by ligating a *Sal*I digested KE DNA fragment into pNP-K. Clone pNP-KKTC, shown in Figure 3D, pNP-KKTV, shown in Figure 3E, pNP-EETC, shown in Figure 3F; and pNP-EETV, shown in Figure 3G, were obtained by ligating a *Sma*I/*Bam*HI digested KE

fragment from the conserved region (KEcon) or from the variable region (KEvar) into pNP-KK or pNP-EE.

The pNP clones were *Hind*III /*Kpn*I digested from the expression vectors, and ligated into the *Hind*III/*Kpn*I cloning site of the transformation vector pGA482G, resulting in clones pTi-NP-K, pTi-NP-KK, pTi-NP-EE, pTi-NP-KKTC, pTi-NP-KKTV, pTi-NP-EETC and pTi-NP-EETV. Cesium chloride purified pTi-NP-clones were then used for host cell transformation by particle gun bombardment.

Example 4 - Amplification and Cloning of Full Length Translatable and Nontranslatable KE

Two full-length KE-CP constructs, shown in Figure 4, start from the first CP cut site which is 60 nt upstream from the second CP cut site. The primers used for amplification and construction of pEPJ-TL KE and pEPJ-NTL KE are shown in Table 3.

Table 3

PRSV Strain	Product (bp)	Primer Sequence (SEQ ID NO)
TL KE	921	
55'KETL		5'AGCTAAccatggAATCAAGGAGCACTGATGATTATC 3' (SEQ ID NO: 31)
3'KE10117		5'ATTTggatcccgggGTTGCGCATGCCCAGGAGAGAG 3' (SEQ ID NO: 32)
NTL KE	921	
5'KENTL		5' AGCTAAccatggAATAATGGAGCACTGATGATTATC 3' (SEQ ID NO: 33)
3'KE10117		5'ATTTggatcccgggGTTGCGCATGCCCAGGAGAGAG 3' (SEQ ID NO: 34)

Restriction enzyme sequence is shown in small letters; the stop codon is shown in caps, without underline; viral sequences are underlined.

Following amplification, the *Nco*I/*Bam*HI digested PCR *KECP* fragments were ligated into pEPJ vector, as shown in Figure 4. Using

*Hind*III/*Kpn*I, the expression cassette was then subcloned into the transformation vector pGA482G.

Example 5 -Amplification and Cloning of MEX CP

The primers used for amplification and preparation of construct pEPJ-MEX CP are shown in Table 4.

Table 4

PRSV Strain	Product (bp)	Primer Sequence (SEQ ID NO)
NTL Mex		
5'MEXXbaNco	855	5'CGAtctagaccattggAATAATGATCCAAGAATGAAGC 3' (SEQ ID NO: 35)
3'MEXBAM		5'CTTAggatccGTTGCGCATACCCAGGAGAGA 3' 3' (SEQ ID NO: 36)

Restriction enzyme sequence is shown in small letters; the stop codon is shown in caps, without underline; viral sequences are underlined.

Example 6 - Transformation of Papaya with *PRSV-CP* DNA Constructs

Papaya embryos were bombarded with DNA constructs prepared as described above and shown in Figures 2-5. The transformation procedure was followed as described in Cai et al., "A Protocol for Efficient Transformation and Regeneration of *Carica papaya L. In Vitro*," Cell Devel. Biol-Plant 35: 61-69 (1999), which is hereby incorporated by reference in its entirety. Plasmid DNA was purified by ethidium bromide CsCl gradient (Ausubel et al., "CsCl/Ethidium Bromide Preparations of Plasmid DNA," Current Protocols in Molec Biol. unit 2.9.1-2.9.20 (1995), which is hereby incorporated by reference in its entirety), ethanol precipitated and suspended in water. Immature zygotic embryos were extracted from seeds of immature green 'Sunrise' or 'Kapoho' papaya and placed on induction medium and kept in the dark. Zygotic embryos with their somatic embryo clusters were placed on Whatman #2 filter paper and spread. The somatic embryos were allowed to proliferate, and following this, the embryos were spread firmly onto fresh filter paper and bombarded with tungsten-coated plasmid DNA. Seven days after bombardment, materials were transferred to induction medium

containing kanamycin at 75 mg/L. After four weeks, the kanamycin level was raised to 150 mg/L. After a few weeks in kanamycin medium, actively growing embryo clusters were transferred to kanamycin-free medium. When the embryos developed a pale ivory color and appeared as finger-like extensions, they were transferred to maturation medium for two to four weeks. Mature somatic embryos were transferred to germination medium and then developed into plantlets with dark green leaves and root initials. Those plantlets were transferred to baby jars with rooting medium and transferred to the greenhouse.

Transgenic lines from the germination medium were analyzed by PCR to confirm that the virus gene was in the plantlets. Northern blots were carried out to detect the level of RNA expressed in transgenic lines, and the copy number of the transgene in the transgenic plants was determined by Southern blot analysis.

Following transfer to the greenhouse, transgenic plants were challenged with the KE strain of PRSV. Plants were thereafter monitored for viral symptoms. If no disease symptoms appeared after approximately 4 weeks post-inoculation, those plants were challenged with a different PRSV strain to test for cross-resistance.

Example 7 - Resistance Imparted to PRSV by Transgenes

219 transgenic lines containing the various PRSV DNA constructs of the present invention, as described above, were transferred to the greenhouse. Inoculation with KE virus was carried out on 90 plant lines transformed with at least one KE-containing DNA construct. Of those 90 lines challenged with PRSV-KE, 26 lines showed resistance and 64 lines were susceptible.

Although preferred embodiments have been depicted and described in detail herein, it will be apparent to those skilled in the relevant art that various modifications, additions, substitutions, and the like can be made without departing from the spirit of the invention and these are therefore considered to be within the scope of the invention as defined in the claims which follow.

WHAT IS CLAIMED:

1. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein, wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 1; 2) encodes an amino acid having SEQ ID NO: 2; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 1 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 1 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

2. A DNA construct comprising:
the nucleic acid molecule according to claim 1 and
an operably linked promoter and 3' regulatory region.

3. A DNA expression vector comprising:
the DNA construct according to claim 2.

4. A host cell transduced with a DNA construct according to claim 2.

5. A host cell according to claim 4, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

6. A transgenic plant transformed with a DNA construct according to claim 2.

7. A transgenic plant according to claim 6, wherein the plant is papaya.

8. A transgenic plant seed transformed with a DNA construct according to claim 2.

9. A transgenic plant seed according to claim 8, wherein the plant is papaya.

10. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 3; 2) encodes an amino acid having SEQ ID NO: 4; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 3 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 3 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

11. A DNA construct comprising:
the nucleic acid molecule according to claim 10 and
an operably linked promoter and 3' regulatory region.

12. An expression vector comprising the DNA construct of claim 11.

13. A host cell transduced with a DNA construct according to claim 11.

14. A host cell according to claim 13, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

15. A transgenic plant transformed with a DNA construct according to claim 11.

16. A transgenic plant according to claim 15, wherein the plant is papaya.

17. A transgenic plant seed transformed with a DNA construct according to claim 11.

18. A transgenic plant seed according to claim 17, wherein the plant is papaya.

19. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein, wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 5; 2) encodes an amino acid having SEQ ID NO: 7; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 5 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 5 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

20. A DNA construct comprising:
the nucleic acid molecule according to claim 19 and
an operably linked promoter and 3' regulatory region.

21. A DNA expression vector comprising:
the DNA construct according to claim 20.

22. A host cell transduced with a DNA construct according to claim 20.

23. A host cell according to claim 22, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

24. A transgenic plant transformed with a DNA construct according to claim 20.

25. A transgenic plant according to claim 24, wherein the plant is papaya.

26. A transgenic plant seed transformed with a DNA construct according to claim 20.

27. A transgenic plant seed according to claim 26, wherein the plant is papaya.

28. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 6; 2) encodes an amino acid having SEQ ID NO: 8; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 6 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 6 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

29. A DNA construct comprising:
the nucleic acid molecule according to claim 28 and
an operably linked promoter and 3' regulatory region.

30. An expression vector comprising the DNA construct of claim 29.

31. A host cell transduced with a DNA construct according to claim 29.

32. A host cell according to claim 31, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

33. A transgenic plant transformed with a DNA construct according to claim 29.

34. A transgenic plant according to claim 33, wherein the plant is papaya.

35. A transgenic plant seed transformed with a DNA construct according to claim 29.

36. A transgenic plant seed according to claim 35, wherein the plant is papaya.

37. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein, wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 11; 2) encodes an amino acid having SEQ ID NO: 12; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 11 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 11 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

38. A DNA construct comprising:
the nucleic acid molecule according to claim 37 and
an operably linked promoter and 3' regulatory region.

39. A DNA expression vector comprising:
the DNA construct according to claim 38.

40. A host cell transduced with a DNA construct according to claim 38.

41. A host cell according to claim 40, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

42. A transgenic plant transformed with a DNA construct according to claim 38.

43. A transgenic plant according to claim 42, wherein the plant is papaya.

44. A transgenic plant seed transformed with a DNA construct according to claim 38.

45. A transgenic plant seed according to claim 44, wherein the plant is papaya.

46. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 13; 2) encodes an amino acid having SEQ ID NO: 14; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 13 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 13 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

47. A DNA construct comprising:
the nucleic acid molecule according to claim 46 and
an operably linked promoter and 3' regulatory region.

48. An expression vector comprising the DNA construct of claim 47.

49. A host cell transduced with a DNA construct according to claim 47.

50. A host cell according to claim 49, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

51. A transgenic plant transformed with a DNA construct according to claim 47.

52. A transgenic plant according to claim 51, wherein the plant is papaya.

53. A transgenic plant seed transformed with a DNA construct according to claim 47.

54. A transgenic plant seed according to claim 53, wherein the plant is papaya.

55. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein, wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 15; 2) encodes an amino acid having SEQ ID NO: 16; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 15 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 15 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

56. A DNA construct comprising:
the nucleic acid molecule according to claim 55 and
an operably linked promoter and 3' regulatory region.

57. A DNA expression vector comprising:
the DNA construct according to claim 56.

58. A host cell transduced with a DNA construct according to claim 56.

59. A host cell according to claim 58, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

60. A transgenic plant transformed with a DNA construct according to claim 56.

61. A transgenic plant according to claim 60, wherein the plant is papaya.

62. A transgenic plant seed transformed with a DNA construct according to claim 56.

63. A transgenic plant seed according to claim 62, wherein the plant is papaya.

64. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 17; 2) encodes an amino acid having SEQ ID NO: 18; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 17 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 17 under stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

65. A DNA construct comprising:

the nucleic acid molecule according to claim 64 and an operably linked promoter and 3' regulatory region.

66. An expression vector comprising the DNA construct of claim 65.

67. A host cell transduced with a DNA construct according to claim 65.

68. A host cell according to claim 67, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

69. A transgenic plant transformed with a DNA construct according to claim 65.

70. A transgenic plant according to claim 69, wherein the plant is papaya.

71. A transgenic plant seed transformed with a DNA construct according to claim 65.

72. A transgenic plant seed according to claim 71, wherein the plant is papaya.

73. An isolated nucleic acid molecule encoding a papaya ringspot virus coat protein wherein the nucleic acid molecule either: 1) has a nucleic acid sequence of SEQ ID NO: 19; 2) encodes an amino acid having SEQ ID NO: 20; 3) has a nucleotide sequence that is at least 85% similar to the nucleotide sequence of SEQ ID NO: 19 by basic BLAST using default parameters analysis; or 4) hybridizes to the nucleotide sequence of SEQ ID NO: 19 under

stringent conditions characterized by a hybridization buffer comprising 5X SSC buffer at a temperature of 45°C.

74. A DNA construct comprising:
the nucleic acid molecule according to claim 73 and
an operably linked promoter and 3' regulatory region.

75. An expression vector comprising the DNA construct of claim 74.

76. A host cell transduced with a DNA construct according to claim 74.

77. A host cell according to claim 76, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

78. A transgenic plant transformed with a DNA construct according to claim 74.

79. A transgenic plant according to claim 78, wherein the plant is papaya.

80. A transgenic plant seed transformed with a DNA construct according to claim 74.

81. A transgenic plant seed according to claim 80, wherein the plant is papaya.

82. A DNA construct comprising:
a plurality of trait DNA molecules at least some of which have a length that is insufficient to impart that trait to plants transformed with that trait

DNA molecule, but said plurality of trait DNA molecules collectively impart their traits to plants transformed with said DNA construct and effect silencing of the DNA construct, wherein the trait is disease resistance and the trait DNA molecules are derived from a gene encoding a papaya ringspot virus coat protein in a papaya ringspot virus strain selected from the group consisting of TH, KE, KA, ME, YK, BR, JA, OA, VE, and PA.

83. A DNA construct according to claim 82, wherein one or more of the trait DNA molecules are selected from the group consisting of the variable regions and conserved regions of said papaya ringspot viral coat proteins.

84. The DNA construct according to claim 82, wherein one or more of the trait DNA molecules are in the sense (5'→3') orientation.

85. The DNA construct according to claim 82, wherein one or more of the trait DNA molecules are inserted in the antisense (3'→5') orientation.

86. An expression vector comprising:
the DNA construct according to claim 82.

87. A host cell transduced with a DNA construct according to claim 82.

88. A host cell according to claim 87, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

89. A transgenic plant transformed with a DNA construct according to claim 82.

90. A transgenic plant according to claim 89, wherein the plant is papaya.

91. A transgenic plant seed transformed with a DNA construct according to claim 82.

92. A transgenic plant seed according to claim 91, wherein the plant is papaya.

93. A DNA construct comprising:

a fusion gene comprising:

a trait DNA molecule which has a length that is insufficient to independently impart a desired trait to plants transformed with said trait DNA molecule and

a silencer DNA molecule effective to achieve post-transcriptional gene silencing and operatively coupled to said trait DNA molecule, wherein said trait DNA molecule and said silencer DNA molecule collectively impart the trait to the plants transformed with said DNA construct, and wherein the trait DNA molecules are derived from a gene encoding a papaya ringspot viral coat protein from a papaya ringspot virus strain selected from the group consisting of TH, KE, KA, ME, YK, BR, JA, OA, VE, and PA.

94. A DNA construct according to claim 93, further comprising:

a promoter sequence operatively coupled to said fusion gene and

a termination sequence operatively coupled to said fusion gene to end transcription.

95. A DNA construct according to claim 93, wherein said silencer DNA molecule is selected from the group consisting of a viral DNA molecule, a fluorescence protein encoding DNA molecule, a plant DNA molecule, a viral gene silencer, and combinations thereof.

96. An expression vector comprising:

the DNA construct according to claim 93.

97. A host cell transduced with a DNA construct according to claim 93.

98. A host cell according to claim 97, wherein the cell is selected from the group consisting of a bacterial cell, a virus, a yeast cell, and a plant cell.

99. A transgenic plant transformed with a DNA construct according to claim 93.

100. A transgenic plant according to claim 36, wherein the plant is papaya.

101. A transgenic plant seed transformed with a DNA construct according to claim 93.

102. A transgenic plant according to claim 101, wherein the plant is papaya.

103. A method of imparting resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 2.

104. A method of imparting resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 11.

105. A method of imparting resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 20.

106. A method of imparting viral resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 29.

107. A method of imparting viral resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 38.

108. A method of imparting viral resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 47.

109. A method of imparting viral resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 56.

110. A method of imparting viral resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 65.

111. A method of imparting viral resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 74.

112. A method of imparting viral resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 82.

113. A method of imparting viral resistance to papaya plants against papaya ringspot virus comprising:

transforming a papaya plant with a DNA construct according to claim 93.
